US Secure Hash Algorithms (SHA and SHA-based HMAC and HKDF)

Abstract

The United States of America has adopted a suite of Secure Hash Algorithms (SHAs), including four beyond SHA-1, as part of a Federal Information Processing Standard (FIPS), namely SHA-224, SHA-256, SHA-384, and SHA-512. This document makes open source code performing these SHA hash functions conveniently available to the Internet community. The sample code supports input strings of arbitrary bit length. Much of the text herein was adapted by the authors from FIPS 180-2.

This document replaces RFC 4634, fixing errata and adding code for an HMAC-based extract-and-expand Key Derivation Function, HKDF (RFC 5869). As with RFC 4634, code to perform SHA-based Hashed Message Authentication Codes (HMACs) is also included.

Status of This Memo

This document is not an Internet Standards Track specification; it is published for informational purposes.

This document is a product of the Internet Engineering Task Force (IETF). It represents the consensus of the IETF community. It has received public review and has been approved for publication by the Internet Engineering Steering Group (IESG). Not all documents approved by the IESG are a candidate for any level of Internet Standard; see Section 2 of RFC 5741.

Information about the current status of this document, any errata, and how to provide feedback on it may be obtained at http://www.rfc-editor.org/info/rfc6234.

Table of Contents

1. Overview of Contents

This document includes specifications for the United States of America (USA) Federal Information Processing Standard (FIPS) Secure Hash Algorithms (SHAs), code to implement the SHAs, code to implement HMAC (Hashed Message Authentication Code, [RFC2104]) based on the SHAs, and code to implement HKDF (HMAC-based Key Derivation Function, [RFC5869]) based on HMAC. Specifications for HMAC and HKDF are not included as they appear elsewhere in the RFC series [RFC2104] [RFC5869].

NOTE: Much of the text below is taken from [SHS], and the assertions of the security of the hash algorithms described therein are made by the US Government, the author of [SHS], not by the listed authors of this document. See also [RFC6194] concerning the security of SHA-1.

The text below specifies Secure Hash Algorithms, SHA-224 [RFC3874], SHA-256, SHA-384, and SHA-512, for computing a condensed representation of a message or a data file. (SHA-1 is specified in [RFC3174].) When a message of any length < 2^64 bits (for SHA-224 and SHA-256) or < 2^128 bits (for SHA-384 and SHA-512) is input to one of these algorithms, the result is an output called a message digest. The message digests range in length from 224 to 512 bits, depending on the algorithm. Secure Hash Algorithms are typically used with other cryptographic algorithms, such as digital signature algorithms and keyed-hash authentication codes, the generation of random numbers [RFC4086], or in key derivation functions.

The algorithms specified in this document are called secure because it is computationally infeasible to (1) find a message that corresponds to a given message digest, or (2) find two different messages that produce the same message digest. Any change to a message in transit will, with very high probability, result in a different message digest. This will result in a verification failure when the Secure Hash Algorithm is used with a digital signature algorithm or a keyed-hash message authentication algorithm.

The code provided herein supports input strings of arbitrary bit length. SHA-1's sample code from [RFC3174] has also been updated to handle input strings of arbitrary bit length. Permission is granted for all uses, commercial and non-commercial, of this code.

This document obsoletes [RFC4634], and the changes from that RFC are summarized in the Appendix.

ASN.1 OIDs (Object Identifiers) for the SHA algorithms, taken from [RFC4055], are as follows:

```
id-sha1  OBJECT IDENTIFIER  ::=  { iso(1)
                     identified-organization(3) oiw(14)
                     secsig(3) algorithms(2) 26 }
 id-sha224  OBJECT IDENTIFIER  ::=  {{ joint-iso-itu-t(2)
                     country(16) us(840) organization(1) gov(101)
                     csor(3) nistalgorithm(4) hashalgs(2) 4 }
 id-sha256  OBJECT IDENTIFIER  ::=  { joint-iso-itu-t(2)
                     country(16) us(840) organization(1) gov(101)
                     csor(3) nistalgorithm(4) hashalgs(2) 1 }
 id-sha384  OBJECT IDENTIFIER  ::=  { joint-iso-itu-t(2)
                     country(16) us(840) organization(1) gov(101)
                     csor(3) nistalgorithm(4) hashalgs(2) 2 }
 id-sha512  OBJECT IDENTIFIER  ::=  { joint-iso-itu-t(2)
                     country(16) us(840) organization(1) gov(101)
                     csor(3) nistalgorithm(4) hashalgs(2) 3 }
```

Section 2 below defines the terminology and functions used as building blocks to form these algorithms. Section 3 describes the fundamental operations on words from which these algorithms are built. Section 4 describes how messages are padded up to an integral multiple of the required block size and then parsed into blocks. Section 5 defines the constants and the composite functions used to specify the hash algorithms. Section 6 gives the actual specification for the SHA-224, SHA-256, SHA-384, and SHA-512 functions. Section 7 provides pointers to the specification of HMAC keyed message authentication codes and to the specification of an extract-and-expand key derivation function based on HMAC.

Section 8 gives sample code for the SHA algorithms, for SHA-based HMACs, and for HMAC-based extract-and-expand key derivation function.

2. Notation for Bit Strings and Integers

The following terminology related to bit strings and integers will be used:

a. A hex digit is an element of the set {0, 1, ... , 9, A, ... , F}. A hex digit is the representation of a 4-bit string. Examples: 7 = 0111, A = 1010.

b. A word equals a 32-bit or 64-bit string that may be represented as a sequence of 8 or 16 hex digits, respectively. To convert a word to hex digits, each 4-bit string is converted to its hex equivalent as described in (a) above. Example:

1010 0001 0000 0011 1111 1110 0010 0011 = A103FE23.

Throughout this document, the "big-endian" convention is used when expressing both 32-bit and 64-bit words, so that within each word the most significant bit is shown in the leftmost bit position.

c. An integer may be represented as a word or pair of words.

An integer between 0 and 2^32 - 1 inclusive may be represented as a 32-bit word. The least significant four bits of the integer are represented by the rightmost hex digit of the word representation. Example: the integer 291 = 2^8+2^5+2^1+2^0 = 256+32+2+1 is represented by the hex word 00000123.

The same holds true for an integer between 0 and 2^64-1 inclusive, which may be represented as a 64-bit word.

If Z is an integer, 0 <= z < 2^64, then z = (2^32)x + y where 0 <= x < 2^32 and 0 <= y < 2^32. Since x and y can be represented as words X and Y, respectively, z can be represented as the pair of words (X,Y).

Again, the "big-endian" convention is used and the most significant word is in the leftmost word position for values represented by multiple-words.

d. block = 512-bit or 1024-bit string. A block (e.g., B) may be represented as a sequence of 32-bit or 64-bit words.

3. Operations on Words

The following logical operators will be applied to words in all four hash operations specified herein. SHA-224 and SHA-256 operate on 32-bit words while SHA-384 and SHA-512 operate on 64-bit words.

In the operations below, x<<n is obtained as follows: discard the leftmost n bits of x and then pad the result with n zeroed bits on the right (the result will still be the same number of bits). Similarly, x>>n is obtained as follows: discard the rightmost n bits of x and then prepend the result with n zeroed bits on the left (the result will still be the same number of bits).

a. Bitwise logical word operations

X AND Y = bitwise logical "and" of X and Y.

X OR Y = bitwise logical "inclusive-or" of X and Y.

X XOR Y = bitwise logical "exclusive-or" of X and Y.

NOT X = bitwise logical "complement" of X.

Example:

```
         01101100101110011101001001111011
   XOR   01100101110000010110100110110111
         --------------------------------
     =   00001001011110001011101111001100
```

b. The operation X + Y is defined as follows: words X and Y represent w-bit integers x and y, where 0 <= x < 2^w and 0 <= y < 2^w. For positive integers n and m, let

   n mod m

   be the remainder upon dividing n by m. Compute

   z = (x + y) mod 2^w.

   Then 0 <= z < 2^w. Convert z to a word, Z, and define Z = X + Y.

c. The right shift operation SHR^n(x), where x is a w-bit word and n is an integer with 0 <= n < w, is defined by

   SHR^n(x) = x>>n

d. The rotate right (circular right shift) operation ROTR^n(x), where x is a w-bit word and n is an integer with 0 <= n < w, is defined by

   ROTR^n(x) = (x>>n) OR (x<<(w-n))

e. The rotate left (circular left shift) operation ROTL^n(x), where x is a w-bit word and n is an integer with 0 <= n < w, is defined by

   ROTL^n(X) = (x<<n) OR (x>>(w-n))

   Note the following equivalence relationships, where w is fixed in each relationship:

   ROTL^n(x) = ROTR^(w-n)(x)

   ROTR^n(x) = ROTL^(w-n)(x)

4. Message Padding and Parsing

The hash functions specified herein are used to compute a message digest for a message or data file that is provided as input. The message or data file should be considered to be a bit string. The length of the message is the number of bits in the message (the empty message has length 0). If the number of bits in a message is a multiple of 8, for compactness we can represent the message in hex. The purpose of message padding is to make the total length of a padded message a multiple of 512 for SHA-224 and SHA-256 or a multiple of 1024 for SHA-384 and SHA-512.

The following specifies how this padding shall be performed. As a summary, a "1" followed by m "0"s followed by a 64-bit or 128-bit integer are appended to the end of the message to produce a padded message of length 512*n or 1024*n. The appended integer is the length of the original message. The padded message is then processed by the hash function as n 512-bit or 1024-bit blocks.

4.1. SHA-224 and SHA-256

Suppose a message has length L < 2^64. Before it is input to the hash function, the message is padded on the right as follows:

a. "1" is appended. Example: if the original message is "01010000", this is padded to "010100001".

b. K "0"s are appended where K is the smallest, non-negative solution to the equation

   (L + 1 + K) mod 512 = 448

c. Then append the 64-bit block that is L in binary representation. After appending this block, the length of the message will be a multiple of 512 bits.

   Example: Suppose the original message is the bit string

   01100001 01100010 01100011 01100100 01100101

   After step (a) this gives

   01100001 01100010 01100011 01100100 01100101 1

Since L = 40, the number of bits in the above is 41 and K = 407 "0"s are appended, making the total now 448. This gives the following in hex:

```
61626364 65800000 00000000 00000000
00000000 00000000 00000000 00000000
00000000 00000000 00000000 00000000
00000000 00000000
```

The 64-bit representation of L = 40 is hex 00000000 00000028. Hence the final padded message is the following hex

```
61626364 65800000 00000000 00000000
00000000 00000000 00000000 00000000
00000000 00000000 00000000 00000000
00000000 00000000 00000000 00000028
```

4.2. SHA-384 and SHA-512

Suppose a message has length L < 2^128. Before it is input to the hash function, the message is padded on the right as follows:

a. "1" is appended. Example: if the original message is "01010000", this is padded to "010100001".

b. K "0"s are appended where K is the smallest, non-negative solution to the equation

```
( L + 1 + K ) mod 1024 = 896
```

c. Then append the 128-bit block that is L in binary representation. After appending this block, the length of the message will be a multiple of 1024 bits.

Example: Suppose the original message is the bit string

```
01100001 01100010 01100011 01100100 01100101
```

After step (a) this gives

```
01100001 01100010 01100011 01100100 01100101 1
```

Since L = 40, the number of bits in the above is 41 and K = 855 "0"s are appended, making the total now 896. This gives the following in hex:

```
61626364 65800000 00000000 00000000
00000000 00000000 00000000 00000000
00000000 00000000 00000000 00000000
00000000 00000000 00000000 00000000
00000000 00000000 00000000 00000000
00000000 00000000 00000000 00000000
00000000 00000000 00000000 00000000
```

The 128-bit representation of L = 40 is hex 00000000 00000000 00000000 00000028. Hence the final padded message is the following hex:

```
61626364 65800000 00000000 00000000
00000000 00000000 00000000 00000000
00000000 00000000 00000000 00000000
00000000 00000000 00000000 00000000
00000000 00000000 00000000 00000000
00000000 00000000 00000000 00000000
00000000 00000000 00000000 00000000
00000000 00000000 00000000 00000028
```

5. Functions and Constants Used

The following subsections give the six logical functions and the table of constants used in each of the hash functions.

5.1. SHA-224 and SHA-256

SHA-224 and SHA-256 use six logical functions, where each function operates on 32-bit words, which are represented as x, y, and z. The result of each function is a new 32-bit word.

```
CH( x, y, z) = (x AND y) XOR ( (NOT x) AND z)

MAJ( x, y, z) = (x AND y) XOR (x AND z) XOR (y AND z)

BSIG0(x) = ROTR^2(x) XOR ROTR^13(x) XOR ROTR^22(x)

BSIG1(x) = ROTR^6(x) XOR ROTR^11(x) XOR ROTR^25(x)

SSIG0(x) = ROTR^7(x) XOR ROTR^18(x) XOR SHR^3(x)

SSIG1(x) = ROTR^17(x) XOR ROTR^19(x) XOR SHR^10(x)
```

SHA-224 and SHA-256 use the same sequence of sixty-four constant 32-bit words, K0, K1, ..., K63. These words represent the first 32 bits of the fractional parts of the cube roots of the first sixty-four prime numbers. In hex, these constant words are as follows (from left to right):

```
428a2f98 71374491 b5c0fbcf e9b5dba5
3956c25b 59f111f1 923f82a4 ab1c5ed5

90befffa a4506ceb bef9a3f7 c67178f2
```

5.2. SHA-384 and SHA-512

SHA-384 and SHA-512 each use six logical functions, where each function operates on 64-bit words, which are represented as x, y, and z. The result of each function is a new 64-bit word.

```
CH( x, y, z) = (x AND y) XOR ( (NOT x) AND z)

MAJ( x, y, z) = (x AND y) XOR (x AND z) XOR (y AND z)

BSIG0(x) = ROTR^28(x) XOR ROTR^34(x) XOR ROTR^39(x)

BSIG1(x) = ROTR^14(x) XOR ROTR^18(x) XOR ROTR^41(x)

SSIG0(x) = ROTR^1(x) XOR ROTR^8(x) XOR SHR^7(x)

SSIG1(x) = ROTR^19(x) XOR ROTR^61(x) XOR SHR^6(x)
```

SHA-384 and SHA-512 use the same sequence of eighty constant 64-bit words, K0, K1, ... K79. These words represent the first 64 bits of the fractional parts of the cube roots of the first eighty prime numbers. In hex, these constant words are as follows (from left to right):

```
428a2f98d728ae22 7137449123ef65cd b5c0fbcfec4d3b2f e9b5dba58189dbbc

6. Computing the Message Digest

The output of each of the secure hash functions, after being applied to a message of N blocks, is the hash quantity H(N). For SHA-224 and SHA-256, H(i) can be considered to be eight 32-bit words, H(i)0, H(i)1, ... H(i)7. For SHA-384 and SHA-512, it can be considered to be eight 64-bit words, H(i)0, H(i)1, ..., H(i)7.

As described below, the hash words are initialized, modified as each message block is processed, and finally concatenated after processing the last block to yield the output. For SHA-256 and SHA-512, all of the H(N) variables are concatenated while the SHA-224 and SHA-384 hashes are produced by omitting some from the final concatenation.

6.1. SHA-224 and SHA-256 Initialization

For SHA-224, the initial hash value, H(0), consists of the following 32-bit words in hex:

```
H(0)0 = c1059ed8
H(0)1 = 367cd507
H(0)2 = 3070dd17
H(0)3 = f70e5939
H(0)4 = ffc00b31
H(0)5 = 68581511
H(0)6 = 64f98fa7
H(0)7 = befa4fa4
```

For SHA-256, the initial hash value, H(0), consists of the following eight 32-bit words, in hex. These words were obtained by taking the first 32 bits of the fractional parts of the square roots of the first eight prime numbers.

```
H(0)0 = 6a09e667
H(0)1 = bb67ae85
H(0)2 = 3c6ef372
H(0)3 = a54ff53a
H(0)4 = 510e527f
H(0)5 = 9b05688c
H(0)6 = 1f83d9ab
H(0)7 = 5be0cd19
```

6.2. SHA-224 and SHA-256 Processing

SHA-224 and SHA-256 perform identical processing on message blocks and differ only in how H(0) is initialized and how they produce their final output. They may be used to hash a message, M, having a length of L bits, where 0 <= L < 2^64. The algorithm uses (1) a message schedule of sixty-four 32-bit words, (2) eight working variables of 32 bits each, and (3) a hash value of eight 32-bit words.

The words of the message schedule are labeled W0, W1, ..., W63. The eight working variables are labeled a, b, c, d, e, f, g, and h. The words of the hash value are labeled H(i)0, H(i)1, ..., H(i)7, which will hold the initial hash value, H(0), replaced by each successive intermediate hash value (after each message block is processed), H(i), and ending with the final hash value, H(N), after all N blocks are processed. They also use two temporary words, T1 and T2.

The input message is padded as described in Section 4.1 above, then parsed into 512-bit blocks that are considered to be composed of sixteen 32-bit words M(i)0, M(i)1, ..., M(i)15. The following computations are then performed for each of the N message blocks. All addition is performed modulo 2^32.

For i = 1 to N

1. Prepare the message schedule W:

```
   For t = 0 to 15
      Wt = M(i)t
   For t = 16 to 63
      Wt = SSIG1(W(t-2)) + W(t-7) + SSIG0(w(t-15)) + W(t-16)
```

2. Initialize the working variables:
   a = H(i-1)0
   b = H(i-1)1
   c = H(i-1)2
   d = H(i-1)3
   e = H(i-1)4
   f = H(i-1)5
   g = H(i-1)6
   h = H(i-1)7

3. Perform the main hash computation:
   For t = 0 to 63
      T1 = h + BSIG1(e) + CH(e,f,g) + Kt + Wt
      T2 = BSIG0(a) + MAJ(a,b,c)
      h = g
      g = f
      f = e
      e = d + T1
      d = c
      c = b
      b = a
      a = T1 + T2

4. Compute the intermediate hash value H(i)
   H(i)0 = a + H(i-1)0
   H(i)1 = b + H(i-1)1
   H(i)2 = c + H(i-1)2
   H(i)3 = d + H(i-1)3
   H(i)4 = e + H(i-1)4
   H(i)5 = f + H(i-1)5
   H(i)6 = g + H(i-1)6
   H(i)7 = h + H(i-1)7

After the above computations have been sequentially performed for all of the blocks in the message, the final output is calculated. For SHA-256, this is the concatenation of all of H(N)0, H(N)1, through H(N)7. For SHA-224, this is the concatenation of H(N)0, H(N)1, through H(N)6.

6.3. SHA-384 and SHA-512 Initialization

For SHA-384, the initial hash value, H(0), consists of the following eight 64-bit words, in hex. These words were obtained by taking the first 64 bits of the fractional parts of the square roots of the ninth through sixteenth prime numbers.

```
H(0)0 = cbbb9d5dc1059ed8
H(0)1 = 629a292a367cd507
H(0)2 = 9159015a3070dd17
H(0)3 = 152fecd8f70e5939
H(0)4 = 67332667ffc00b31
H(0)5 = 8eb44a8768581511
H(0)6 = db0c2e0d64f98fa7
H(0)7 = 47b5481dbefa4fa4
```

For SHA-512, the initial hash value, H(0), consists of the following eight 64-bit words, in hex. These words were obtained by taking the first 64 bits of the fractional parts of the square roots of the first eight prime numbers.

```
H(0)0 = 6a09e667f3bcc908
H(0)1 = bb67ae8584caa73b
H(0)2 = 3c6ef372fe94f82b
H(0)3 = a54ff53a5f1d36f1
H(0)4 = 510e527fade682d1
H(0)5 = 9b05688c2b3e6c1f
H(0)6 = 1f83d9abfb41bd6b
H(0)7 = 5be0cd19137e2179
```

6.4. SHA-384 and SHA-512 Processing

SHA-384 and SHA-512 perform identical processing on message blocks and differ only in how H(0) is initialized and how they produce their final output. They may be used to hash a message, M, having a length of L bits, where 0 <= L < 2^128. The algorithm uses (1) a message schedule of eighty 64-bit words, (2) eight working variables of 64 bits each, and (3) a hash value of eight 64-bit words.

The words of the message schedule are labeled W0, W1, ..., W79. The eight working variables are labeled a, b, c, d, e, f, g, and h. The words of the hash value are labeled H(i)0, H(i)1, ..., H(i)7, which will hold the initial hash value, H(0), replaced by each successive intermediate hash value (after each message block is processed), H(i), and ending with the final hash value, H(N) after all N blocks are processed.

The input message is padded as described in Section 4.2 above, then parsed into 1024-bit blocks that are considered to be composed of sixteen 64-bit words M(i)0, M(i)1, ..., M(i)15. The following computations are then performed for each of the N message blocks. All addition is performed modulo 2^64.

```
For i = 1 to N

   1. Prepare the message schedule W:
      For t = 0 to 15
         Wt = M(i)t
      For t = 16 to 79
         Wt = SSIG1(W(t-2)) + W(t-7) + SSIG0(W(t-15)) + W(t-16)

   2. Initialize the working variables:
      a = H(i-1)0
      b = H(i-1)1
      c = H(i-1)2
      d = H(i-1)3
      e = H(i-1)4
      f = H(i-1)5
      g = H(i-1)6
      h = H(i-1)7

   3. Perform the main hash computation:
      For t = 0 to 79
         T1 = h + BSIG1(e) + CH(e,f,g) + Kt + Wt
         T2 = BSIG0(a) + MAJ(a,b,c)
         h = g
         g = f
         f = e
         e = d + T1
         d = c
         c = b
         b = a
         a = T1 + T2

      4. Compute the intermediate hash value H(i)
         H(i)0 = a + H(i-1)0
         H(i)1 = b + H(i-1)1
         H(i)2 = c + H(i-1)2
         H(i)3 = d + H(i-1)3
         H(i)4 = e + H(i-1)4
         H(i)5 = f + H(i-1)5
         H(i)6 = g + H(i-1)6
         H(i)7 = h + H(i-1)7
```

After the above computations have been sequentially performed for all of the blocks in the message, the final output is calculated. For SHA-512, this is the concatenation of all of H(N)0, H(N)1, through H(N)7. For SHA-384, this is the concatenation of H(N)0, H(N)1, through H(N)5.

7. HKDF- and SHA-Based HMACs

Below are brief descriptions and pointers to more complete descriptions and code for (1) SHA-based HMACs and (2) an HMAC-based extract-and-expand key derivation function. Both HKDF and HMAC were devised by Hugo Krawczyk.

7.1. SHA-Based HMACs

HMAC is a method for computing a keyed MAC (Message Authentication Code) using a hash function as described in [RFC2104]. It uses a key to mix in with the input text to produce the final hash.

Sample code is also provided, in Section 8.3 below, to perform HMAC based on any of the SHA algorithms described herein. The sample code found in [RFC2104] was written in terms of a specified text size. Since SHA is defined in terms of an arbitrary number of bits, the sample HMAC code has been written to allow the text input to HMAC to have an arbitrary number of octets and bits. A fixed-length interface is also provided.

7.2. HKDF

HKDF is a specific Key Derivation Function (KDF), that is, a function of initial keying material from which the KDF derives one or more cryptographically strong secret keys. HKDF, which is described in [RFC5869], is based on HMAC.

Sample code for HKDF is provided in Section 8.4 below.

8. C Code for SHAs, HMAC, and HKDF

Below is a demonstration implementation of these secure hash functions in C. Section 8.1 contains the header file sha.h that declares all constants, structures, and functions used by the SHA and HMAC functions. It includes conditionals based on the state of definition of USE_32BIT_ONLY that, if that symbol is defined at compile time, avoids 64-bit operations. It also contains sha-private.h that provides some declarations common to all the SHA functions. Section 8.2 contains the C code for sha1.c, sha224-256.c, sha384-512.c, and usha.c. Section 8.3 contains the C code for the HMAC functions, and Section 8.4 contains the C code for HKDF. Section 8.5 contains a test driver to exercise the code.

For each of the digest lengths $$$, there is the following set of constants, a structure, and functions:

```
   Constants:
      SHA$$$HashSize      number of octets in the hash
      SHA$$$HashSizeBits  number of bits in the hash
      SHA$$$_Message_Block_Size
                          number of octets used in the intermediate
                          message blocks
      Most functions return an enum value that is one of:
        shaSuccess(0)      on success
        shaNull(1)         when presented with a null pointer parameter
        shaInputTooLong(2)  when the input data is too long
        shaStateError(3)   when SHA$$$Input is called after
                          SHA$$$FinalBits or SHA$$$Result

   Structure:
      typedef SHA$$$Context
                          an opaque structure holding the complete state
                          for producing the hash

   Functions:
      int SHA$$$Reset(SHA$$$Context *context);
            Reset the hash context state.
      int SHA$$$Input(SHA$$$Context *context, const uint8_t *octets,
                  unsigned int bytecount);
            Incorporate bytecount octets into the hash.
      int SHA$$$FinalBits(SHA$$$Context *, const uint8_t octet,
                  unsigned int bitcount);
            Incorporate bitcount bits into the hash.  The bits are in
            the upper portion of the octet.  SHA$$$Input() cannot be
            called after this.
      int SHA$$$Result(SHA$$$Context *,
                  uint8_t Message_Digest[SHA$$$HashSize]);
            Do the final calculations on the hash and copy the value
            into Message_Digest.

   In addition, functions with the prefix USHA are provided that take a
   SHAversion value (SHA$$$) to select the SHA function suite.  They add
   the following constants, structure, and functions:

   Constants:
      shaBadParam(4)      constant returned by USHA functions when
                          presented with a bad SHAversion (SHA$$$)
                          parameter or other illegal parameter values
      USAMaxHashSize      maximum of the SHA hash sizes
      SHA$$$              SHAversion enumeration values, used by USHA,
                          HMAC, and HKDF functions to select the SHA
                          function suite
```

```
   Structure:
      typedef USHAContext
                           an opaque structure holding the complete state
                           for producing the hash

   Functions:
      int USHAReset(USHAContext *context, SHAversion whichSha);
            Reset the hash context state.
      int USHAInput(USHAContext context*,
                  const uint8_t *bytes, unsigned int bytecount);
            Incorporate bytecount octets into the hash.
      int USHAFinalBits(USHAContext *context,
                  const uint8_t bits, unsigned int bitcount);
            Incorporate bitcount bits into the hash.
      int USHAResult(USHAContext *context,
                  uint8_t Message_Digest[USHAMaxHashSize]);
            Do the final calculations on the hash and copy the value
            into Message_Digest.  Octets in Message_Digest beyond
            USHAHashSize(whichSha) are left untouched.
      int USHAHashSize(enum SHAversion whichSha);
            The number of octets in the given hash.
      int USHAHashSizeBits(enum SHAversion whichSha);
            The number of bits in the given hash.
      int USHABlockSize(enum SHAversion whichSha);
            The internal block size for the given hash.
      const char *USHAHashName(enum SHAversion whichSha);
            This function will return the name of the given SHA
            algorithm as a string.

   The HMAC functions follow the same pattern to allow any length of
   text input to be used.

   Structure:
      typedef HMACContext an opaque structure holding the complete state
                           for producing the keyed message digest (MAC)

   Functions:
      int hmacReset(HMACContext *ctx, enum SHAversion whichSha,
                  const unsigned char *key, int key_len);
            Reset the MAC context state.
      int hmacInput(HMACContext *ctx, const unsigned char *text,
                  int text_len);
            Incorporate text_len octets into the MAC.
      int hmacFinalBits(HMACContext *ctx, const uint8_t bits,
                  unsigned int bitcount);
            Incorporate bitcount bits into the MAC.
      int hmacResult(HMACContext *ctx,
                  uint8_t Message_Digest[USHAMaxHashSize]);
```

```
        Do the final calculations on the MAC and copy the value into
        Message_Digest.  Octets in Message_Digest beyond
        USHAHashSize(whichSha) are left untouched.
```

In addition, a combined interface is provided, similar to that shown in [RFC2104], that allows a fixed-length text input to be used.

```
   int hmac(SHAversion whichSha,
            const unsigned char *text, int text_len,
            const unsigned char *key, int key_len,
            uint8_t Message_Digest[USHAMaxHashSize]);
        Calculate the given digest for the given text and key, and
        return the resulting MAC.  Octets in Message_Digest beyond
        USHAHashSize(whichSha) are left untouched.
```

The HKDF functions follow the same pattern to allow any length of text input to be used.

```
Structure:
   typedef HKDFContext an opaque structure holding the complete state
                       for producing the keying material
Functions:
   int hkdfReset(HKDFContext *context, enum SHAversion whichSha,
            const unsigned char *salt, int salt_len)
        Reset the key derivation state and initialize it with the
        salt_len octets of the optional salt.
   int hkdfInput(HKDFContext *context, const unsigned char *ikm,
            int ikm_len)
        Incorporate ikm_len octets into the entropy extractor.
   int hkdfFinalBits(HKDFContext *context, uint8_t ikm_bits,
            unsigned int ikm_bit_count)
        Incorporate ikm_bit_count bits into the entropy extractor.
   int hkdfResult(HKDFContext *context,
            uint8_t prk[USHAMaxHashSize],
            const unsigned char *info, int info_len,
            uint8_t okm[ ], int okm_len)
        Finish the HKDF extraction and perform the final HKDF
        expansion, storing the okm_len octets into output keying
        material (okm).  Optionally store the pseudo-random key
        (prk) that is generated internally.
```

In addition, combined interfaces are provided, similar to that shown in [RFC5869], that allows a fixed-length text input to be used.

```
   int hkdfExtract(SHAversion whichSha,
            const unsigned char *salt, int salt_len,
            const unsigned char *ikm, int ikm_len,
            uint8_t prk[USHAMaxHashSize])
```

Perform HKDF extraction, combining the salt_len octets of the optional salt with the ikm_len octets of the input keying material (ikm) to form the pseudo-random key prk. The output prk must be large enough to hold the octets appropriate for the given hash type.

```
int hkdfExpand(SHAversion whichSha,
               const uint8_t prk[ ], int prk_len,
               const unsigned char *info, int info_len,
               uint8_t okm[ ], int okm_len)
```

Perform HKDF expansion, combining the prk_len octets of the pseudo-random key prk with the info_len octets of info to form the okm_len octets stored in okm.

```
int hkdf(SHAversion whichSha,
               const unsigned char *salt, int salt_len,
               const unsigned char *ikm, int ikm_len,
               const unsigned char *info, int info_len,
               uint8_t okm[ ], int okm_len)
```

This combined interface performs both HKDF extraction and expansion. The variables are the same as in hkdfExtract() and hkdfExpand().

8.1. The Header Files

8.1.1. The .h file

The following sha.h file, as stated in the comments within the file, assumes that <stdint.h> is available on your system. If it is not, you should change to including <stdint-example.h>, provided in Section 8.1.2, or the like.

```

/*
 *  Description:
 *      This file implements the Secure Hash Algorithms
 *      as defined in the U.S. National Institute of Standards
 *      and Technology Federal Information Processing Standards
 *      Publication (FIPS PUB) 180-3 published in October 2008
 *      and formerly defined in its predecessors, FIPS PUB 180-1
 *      and FIP PUB 180-2.
 *
 *      A combined document showing all algorithms is available at
 *              http://csrc.nist.gov/publications/fips/
 *                     fips180-3/fips180-3_final.pdf
 *
 *      The five hashes are defined in these sizes:
 *              SHA-1           20 byte / 160 bit
 *              SHA-224         28 byte / 224 bit
 *              SHA-256         32 byte / 256 bit
 *              SHA-384         48 byte / 384 bit
 *              SHA-512         64 byte / 512 bit
 *
```

```
 *  Compilation Note:
 *    These files may be compiled with two options:
 *        USE_32BIT_ONLY - use 32-bit arithmetic only, for systems
 *                         without 64-bit integers
 *
 *        USE_MODIFIED_MACROS - use alternate form of the SHA_Ch()
 *                         and SHA_Maj() macros that are equivalent
 *                         and potentially faster on many systems
 *
 */

#include <stdint.h>
/*
 * If you do not have the ISO standard stdint.h header file, then you
 * must typedef the following:
 *    name              meaning
 *  uint64_t         unsigned 64-bit integer
 *  uint32_t         unsigned 32-bit integer
 *  uint8_t          unsigned 8-bit integer (i.e., unsigned char)
 *  int_least16_t    integer of >= 16 bits
 *

8.1.2. stdint-example.h

If your system does not have <stdint.h>, the following should be adequate as a substitute for compiling the other code in this document.

```
/********************** stdint-example.h **********************/
/**** Use this file if your system does not have a stdint.h. ***/
/****************** See RFC 6234 for details. ******************/
#ifndef STDINT_H
#define STDINT_H

typedef unsigned long long uint64_t;    /* unsigned 64-bit integer */
typedef unsigned int       uint32_t;    /* unsigned 32-bit integer */
typedef unsigned char      uint8_t;     /* unsigned 8-bit integer */
                                        /* (i.e., unsigned char) */
typedef int int_least32_t;              /* integer of >= 32 bits */
typedef short int_least16_t;            /* integer of >= 16 bits */

#endif /* STDINT_H */
```

8.1.3. sha-private.h

The sha-private.h header file contains definitions that should only be needed internally in the other code in this document. These definitions should not be needed in application code calling the code provided in this document.

```
/********************** sha-private.h **********************/
/****************** See RFC 6234 for details. ******************/
#ifndef _SHA_PRIVATE__H
#define _SHA_PRIVATE__H
/*
 * These definitions are defined in FIPS 180-3, section 4.1.
 * Ch() and Maj() are defined identically in sections 4.1.1,
 * 4.1.2, and 4.1.3.
 *
 * The definitions used in FIPS 180-3 are as follows:
 */
```

```
#ifndef USE_MODIFIED_MACROS
#define SHA_Ch(x,y,z)        (((x) & (y)) ^ ((~(x)) & (z)))
#define SHA_Maj(x,y,z)       (((x) & (y)) ^ ((x) & (z)) ^ ((y) & (z)))
#else /* USE_MODIFIED_MACROS */
/*
 * The following definitions are equivalent and potentially faster.
 */

#define SHA_Ch(x, y, z)      (((x) & ((y) ^ (z))) ^ (z))
#define SHA_Maj(x, y, z)     (((x) & ((y) | (z))) | ((y) & (z)))

#endif /* USE_MODIFIED_MACROS */

#define SHA_Parity(x, y, z)  ((x) ^ (y) ^ (z))

#endif /* _SHA_PRIVATE__H */
```

8.2. The SHA Code

This code is primarily intended as expository reference code and could be optimized further. For example, the assignment rotations through the variables a, b, ..., h could be treated as a cycle and the loop unrolled, rather than doing the explicit copying.

Note that there are alternative representations of the Ch() and Maj() functions controlled by an ifdef.

8.2.1. sha1.c

```
/*************************** sha1.c ***************************/
/***************** See RFC 6234 for details. ******************/
/* Copyright (c) 2011 IETF Trust and the persons identified as */
/* authors of the code.  All rights reserved.                  */
/* See sha.h for terms of use and redistribution.              */

/*
 *  Description:
 *      This file implements the Secure Hash Algorithm SHA-1
 *      as defined in the U.S. National Institute of Standards
 *      and Technology Federal Information Processing Standards
 *      Publication (FIPS PUB) 180-3 published in October 2008
 *      and formerly defined in its predecessors, FIPS PUB 180-1
 *      and FIP PUB 180-2.
 *
 *      A combined document showing all algorithms is available at
 *              http://csrc.nist.gov/publications/fips/
 *                     fips180-3/fips180-3_final.pdf
 *
```

```
 *      The SHA-1 algorithm produces a 160-bit message digest for a
 *      given data stream that can serve as a means of providing a
 *      "fingerprint" for a message.
 *
 *  Portability Issues:
 *      SHA-1 is defined in terms of 32-bit "words".  This code
 *      uses <stdint.h> (included via "sha.h") to define 32- and
 *      8-bit unsigned integer types.  If your C compiler does
 *      not support 32-bit unsigned integers, this code is not
 *      appropriate.
 *
 *  Caveats:
 *      SHA-1 is designed to work with messages less than 2^64 bits
 *      long.  This implementation uses SHA1Input() to hash the bits
 *      that are a multiple of the size of an 8-bit octet, and then
 *      optionally uses SHA1FinalBits() to hash the final few bits of
 *      the input.
 */

8.2.2. sha224-256.c

```
/************************ sha224-256.c ************************/
/***************** See RFC 6234 for details. ******************/
/* Copyright (c) 2011 IETF Trust and the persons identified as */
/* authors of the code.  All rights reserved.                  */
/* See sha.h for terms of use and redistribution.              */

/*
 * Description:
 *   This file implements the Secure Hash Algorithms SHA-224 and
 *   SHA-256 as defined in the U.S. National Institute of Standards
 *   and Technology Federal Information Processing Standards
 *   Publication (FIPS PUB) 180-3 published in October 2008
 *   and formerly defined in its predecessors, FIPS PUB 180-1
 *   and FIP PUB 180-2.
 *
 *   A combined document showing all algorithms is available at
 *       http://csrc.nist.gov/publications/fips/
 *              fips180-3/fips180-3_final.pdf
 *
 *   The SHA-224 and SHA-256 algorithms produce 224-bit and 256-bit
 *   message digests for a given data stream.  It should take about
 *   2**n steps to find a message with the same digest as a given
 *   message and 2**(n/2) to find any two messages with the same
 *   digest, when n is the digest size in bits.  Therefore, this
 *   algorithm can serve as a means of providing a
 *   "fingerprint" for a message.
 *
 * Portability Issues:
 *   SHA-224 and SHA-256 are defined in terms of 32-bit "words".
 *   This code uses <stdint.h> (included via "sha.h") to define 32-
 *   and 8-bit unsigned integer types.  If your C compiler does not
```

```
 *   support 32-bit unsigned integers, this code is not
 *   appropriate.
 *
 * Caveats:
 *   SHA-224 and SHA-256 are designed to work with messages less
 *   than 2^64 bits long.  This implementation uses SHA224/256Input()
 *   to hash the bits that are a multiple of the size of an 8-bit
 *   octet, and then optionally uses SHA224/256FinalBits()
 *   to hash the final few bits of the input.
 */

/* authors of the code.  All rights reserved.                  */
/* See sha.h for terms of use and redistribution.              */

/*
 * Description:
 *   This file implements the Secure Hash Algorithms SHA-384 and
 *   SHA-512 as defined in the U.S. National Institute of Standards
 *   and Technology Federal Information Processing Standards
 *   Publication (FIPS PUB) 180-3 published in October 2008
 *   and formerly defined in its predecessors, FIPS PUB 180-1
 *   and FIP PUB 180-2.
 *
 *   A combined document showing all algorithms is available at
 *       http://csrc.nist.gov/publications/fips/
 *              fips180-3/fips180-3_final.pdf
 *
 *   The SHA-384 and SHA-512 algorithms produce 384-bit and 512-bit
 *   message digests for a given data stream.  It should take about
 *   2**n steps to find a message with the same digest as a given
```

```
 *   message and 2**(n/2) to find any two messages with the same
 *   digest, when n is the digest size in bits.  Therefore, this
 *   algorithm can serve as a means of providing a
 *   "fingerprint" for a message.
 *
 * Portability Issues:
 *   SHA-384 and SHA-512 are defined in terms of 64-bit "words",
 *   but if USE_32BIT_ONLY is #defined, this code is implemented in
 *   terms of 32-bit "words".  This code uses <stdint.h> (included
 *   via "sha.h") to define the 64-, 32- and 8-bit unsigned integer
 *   types.  If your C compiler does not support 64-bit unsigned
 *   integers and you do not #define USE_32BIT_ONLY, this code is
 *   not appropriate.
 *
 * Caveats:
 *   SHA-384 and SHA-512 are designed to work with messages less
 *   than 2^128 bits long.  This implementation uses SHA384/512Input()
 *   to hash the bits that are a multiple of the size of an 8-bit
 *   octet, and then optionally uses SHA384/256FinalBits()
 *   to hash the final few bits of the input.
 *
 */

8.5. The Test Driver

The following code is a main program test driver to exercise the code in sha1.c, sha224-256.c, sha384-512.c, hmac.c, and hkdf.c. The test driver can also be used as a standalone program for generating the hashes. Note that the tests assume that character values are as in [US-ASCII] and a run time check warns if the code appears to have been compiled with some other character system.

See also [SHAVS].

```
/************************* shatest.c *************************/
/***************** See RFC 6234 for details. ******************/
/* Copyright (c) 2011 IETF Trust and the persons identified as */
/* authors of the code.  All rights reserved.                  */
/* See sha.h for terms of use and redistribution.              */

/*
 *  Description:
 *    This file will exercise the SHA code performing
 *      the three tests documented in FIPS PUB 180-3
 *        (http://csrc.nist.gov/publications/fips/
 *         fips180-2/fips180-2withchangenotice.pdf)
 *      one that calls SHAInput with an exact multiple of 512 bits
 *      the seven tests documented for each algorithm in
 *        "The Secure Hash Algorithm Validation System (SHAVS)"
 *        (http://csrc.nist.gov/cryptval/shs/SHAVS.pdf),
 *        three of which are bit-level tests
 *
```

```
 *    These tests have subsequently been moved to pages linked from
 *      http://csrc.nist.gov/groups/ST/toolkit/examples.html
 *
 *    This file will exercise the HMAC SHA1 code performing
 *      the seven tests documented in RFCs [RFC 2202] and [RFC 4231].
 *
 *    This file will exercise the HKDF code performing
 *      the seven tests documented in RFC 4869.
 *
 *    To run the tests and just see PASSED/FAILED, use the -p option.
 *
 *    Other options exercise:
 *      hashing an arbitrary string
 *      hashing a file's contents
 *      a few error test checks
 *      printing the results in raw format
 *
 *  Portability Issues:
 *    None.
 *

9. Security Considerations

This document is intended to provide convenient open source access by the Internet community to the United States of America Federal Information Processing Standard Secure Hash Algorithms (SHAs) [FIPS 180-2], HMACs based thereon, and HKDF. No independent assertion of the security of these functions by the authors for any particular use is intended.

See [RFC6194] for a discussion of SHA-1 Security Considerations.

10. Acknowledgements

Thanks for the corrections to [RFC4634] that were provided by Alfred Hoenes and Jan Andres and to Alfred's comments on the document hereof.

Also to the following in alphabetic order, whose comments lead to improvements in the document: James Carlson, Russ Housley, Tero Kivinen, Juergen Quittek, and Sean Turner.

Appendix: Changes from RFC 4634

The following changes were made to RFC 4634 to produce this document:

1. Add code for HKDF and brief text about HKDF with pointer to [RFC5869].

2. Fix numerous errata filed against [RFC4634] as included below. Note that in no case did the old code return an incorrect hash value.

   2.a. Correct some of the error return values which has erroneously been "shaNull" to the correct "shaInputTooLong" error.

   2.b. Update comments and variable names within the code for consistency and clarity and other editorial changes.

   2.c. The previous code for SHA-384 and SHA-512 would stop after 2^93 bytes (2^96 bits). The fixed code handles up to 2^125 bytes (2^128 bits).

   2.d. Add additional error checking including a run time check in the test driver to detect attempts to run the test driver after compilation using some other character set instead of [US-ASCII].

3. Update boilerplate, remove special license in [RFC4634] as new boilerplate mandates simplified BSD license.

4. Replace MIT version of getopt with new code to satisfy IETF incoming and outgoing license restrictions.

5. Add references to [RFC6194].

6. Other assorted editorial improvements.
